Drug Dosage

The authors and the publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accord with current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new and/or infrequently employed drug.

Fig. 1. Light micrographs of nasal mucosa biopsy specimens, a, b Seemingly normal nasal mucosa (a) from a ‘healthy control’ subject. At higher magnification (b), it becomes obvious that necrotic epithelial cells may be recognized and that cytoplasmic blebs extend from the luminal surface. Note the many blood vessels along the basement membrane, c Low-power micrograph demonstrating the variations in the epithelium, being metaplastic to the right, pseudostratified in the center, and discontinuous at the left margin. Patient with RAOM. d A cluster of epithelial cells bulges from the gland duct in the center, seemingly in an attempt to restore the adjacent injured epithelium. ‘Healthy control’ subject, e, f Low-power micrograph (e) of a biopsy specimen from a patient with RAOM, demonstrating extensive epithelial damage and even some
denudation as well as many blood vessels. At higher magnification (f), it can be recognized that capillaries almost penetrate the thin basement membrane and approach residing epithelial cells. Numerous vascular loops extend into the nasal epithelium which is predominantly metaplastic and form a continuous covering. Gland ducts are seen in the lamina propria. Patient with RAOM. h Remnants of the nasal epithelium are seen to the left, while the basement membrane is denuded to the right. Blood vessels approach the thickened basement membrane. ‘Healthy control’ subject, i Scattered goblet cells may be identified by their red color. Note the discontinuity in the epithelial lining in the center. The glands are separated by collagen bundles. ‘Healthy control’ subject, j Low-power micrograph of nasal mucosa biopsy specimen from a ‘healthy control’ subject. The epithelium to the left is somewhat irregular, but pseudostratified and containing several goblet cells. The epithelial covering in the center is partly necrotic and lacking to the right. Note the fibrosis in the lamina propria to the right. ‘Healthy control’ subject, k Numerous goblet cells may be recognized by their red staining at various depths in the discontinuous epithelial lining. Note the irregular basement membrane. RAOM patient. l Scattered red goblet cells are seen in the metaplastic nasal epithelium. The epithelial lining is continuous, but hides increased intercellular spaces. RAOM patient, m Red-stained goblet cells and inflammatory cells are seen in the depth among the somewhat irregular, mainly pseudostratified epithelium. Several glands in the lamina propria, separated by collagen bundles. ‘Healthy control’ subject, n Goblet cells and inflammatory cells may be recognized in the metaplastic nasal epithelium from a RAOM patient. Note the irregular basement membrane and the collagen bundles in the lamina propria. o Metaplastic epithelium covering the tortuous basement membrane and blood vessels. A microabscess to the top right. A cluster of cells in the lamina propria gland to the right appears necrotic. ‘Healthy control’ subject, p The superficial metaplastic epithelial cells may form a continuous lining that covers the extended extracellular spaces recognized among the few cells. The basement membrane is irregular and is bordered by blood vessels and interposed cells. Seromucous glands in the lamina propria (to the left). RAOM patient.
