Key Words

Intrapancreatic accessory spleen · Nonsecreting endocrine tumor

Abstract

In a large series of nonselected autopsy investigations an accessory spleen was found in 10–30%. The second most common site is the pancreatic tail (17%). We report a case of intrapancreatic accessory spleen misdiagnosed as a nonsecreting neuroendocrine tumor of the pancreas. Nuclear scintigraphy may provide the definitive diagnosis of an intrapancreatic spleen and therefore prevent patients from unnecessary major surgery.

Introduction

An intrapancreatic accessory spleen may be misdiagnosed as a nonsecreting neuroendocrine tumor of the pancreas. An accurate diagnosis is crucial since such an accessory spleen does not require surgical treatment. We report a case of an intrapancreatic accessory spleen with review of the literature.

Case Report

A 67-year-old woman in good general conditions with a family history positive for pancreatic cancer underwent a routine health check. Her personal history was completely uneventful without any symptoms present. Physical examination was normal and laboratory tests revealed normal alpha fetoprotein and carcinoembryonic antigen but a slightly elevated tumor marker CA 19-9 (35 U/ml; normal <27.0 U/ml). Additional laboratory tests such as chromogranin A, neuron-specific enolase, 5-hydroxyindoleacetic acid, pancreatic polypeptide and substance P were ordered and normal beside a slightly elevated pancreatic polypeptide level (437 pg/ml; normal <210 pg/ml). The patient also

underwent a CT scan investigation which showed a $18 \times 15 \times 15$ mm nodular lesion in the tail of the pancreas without any contrast enhancement ([fig. 1](#)). An additional octreotide scan was normal. Because of the abnormal tumor markers CA 19-9 and pancreatic polypeptide, a neuroendocrine tumor was suspected, although the image appearances were not typical. Due to this potentially malignant lesion the patient underwent a left-sided splenopancreatectomy. Intraoperatively, a dark red but soft tumor was found in the tail of the pancreas and the lesion was also confirmed by intraoperative sonography. Postoperative histopathological examination revealed a completely intrapancreatic accessory spleen without any signs of a tumor ([fig. 2](#), [fig. 3](#)). The patient's postoperative recovery was uneventful.

Discussion

During the 5th week of gestation the spleen develops in the dorsal mesogastrium from mesenchymal cells that migrate between the leaves of the mesentery and coalesce [1]. An accessory spleen may arise from isolated cells which rest separated from the main body of the spleen. In a large series of nonselected autopsy investigations an accessory spleen was found in 10–30% [1, 2]. In 1,000 consecutive patients undergoing contrast-enhanced abdominal CT scan an accessory spleen was present in 16% [3]. In 80% the accessory spleen is located at or near the splenic hilum. The second most common site is the pancreatic tail (17%) [2].

Differential diagnosis of a solid pancreas tumor includes pancreatic adenocarcinoma, pancreatic neuroendocrine tumor, solid and papillary epithelial neoplasms and metastasis. Pancreatic endocrine tumors are rare (<10%) and often localized in the head of the pancreas [4, 5]. Due to secretion of biologically active substances, 15–53% of these tumors become symptomatic [4], all others remain initially silent. However 50% of these nonsecreting endocrine tumors are malignant and require surgical resection [6].

In the English language literature only 11 cases of surgical resection of an intrapancreatic accessory spleen have been reported up to now [7]. In most of these cases the intrapancreatic accessory spleen was misdiagnosed as a pancreatic tumor and patients underwent unnecessary surgery. Most intrapancreatic accessory spleens are roundish and have a characteristic homogenous contrast-enhanced appearance on CT scan with well-defined margins. Most often they are small with a diameter of less than 2 cm [8]. However, definitive diagnosis based on imaging can be difficult because CT scan, MRI and ultrasound images of such intrapancreatic spleens are quite similar to those of hypervascular pancreatic tumors, as islet cell tumors and acinar cell carcinoma [9].

Using contrast-enhanced ultrasound, Ota and Ono [9] demonstrated in the hepatosplenic phase that contrast medium is trapped by hepatic and splenic tissue, which may allow to distinguish an intrapancreatic spleen from other lesions. Somatostatin receptor scintigraphy (octreotide scan) has a high sensitivity in detection of gastrointestinal neuroendocrine tumors (70–95%) [10]. However, octreotide scan may also give false-positive results. The presence of somatostatin receptors on the surface of lymphocytes within the splenic tissue, which also bind octreotide with a high affinity, may therefore mimic a neuroendocrine tumor [10, 11]. Heredia et al. [12] diagnosed in three of five patients an intrapancreatic accessory spleen based on the findings of standard gadolinium-enhanced MRI. However, they were not able to exclude other diagnoses with this investigation, including pancreatic neuroendocrine tumors, pancreatic adenocarcinomas, solid and papillary epithelial neoplasms, and metastasis.

The only possibility to differentiate an accessory spleen from a neuroendocrine tumor are nuclear scintigraphic investigations as ^{99m}Tc -sulphur colloid or Tc-tagged

heat-damaged red blood cells scintigraphies. These are investigations which are noninvasive, sensitive and specific for detecting splenic tissue [13, 14].

Conclusion

In asymptomatic homogenous and well-circumscribed tumors in the pancreatic tail an accessory spleen has to be excluded before surgery. Nuclear scintigraphies such as ^{99m}Tc -sulphur colloid or Tc-tagged heat-damaged red blood cells scintigraphies should be definitely routinely used in the preoperative evaluation of nonsecreting pancreatic lesions, particularly those which are located in the body and tail of the pancreas. These imaging modalities may provide the definitive diagnosis of an intrapancreatic spleen and therefore prevent patients from undergoing unnecessary major surgery.
