Brugada syndrome • Cardiac arrest • Liquorice • Hypokalemia

Abstract

Objective: It was the aim of this study to report an aborted cardiac arrest due to ventricular fibrillation and electrocardiographic changes consistent with Brugada syndrome due to liquorice-induced hypokalemia. **Clinical Presentation and Intervention:** Ventricular fibrillation was witnessed in a 50-year-old woman who was admitted to our emergency department with a history of liquorice ingestion, a herbal product. After stopping liquorice ingestion, the Brugada-like electrocardiographic pattern changed progressively with potassium replacement. A diagnosis of Brugada syndrome was made after the ajmaline challenge test. The patient was discharged with an implantable cardioverter defibrillator and had an uneventful follow-up. **Conclusion:** This report illustrates the importance of the investigation for herbal medications in the detailed history of a patient in the cases of electrolyte disturbances and the potential role of hypokalemia in the induction of malignant arrhythmia in Brugada syndrome.

Introduction

Brugada syndrome is characterized with electrocardiographic (ECG) findings of apparent or real right bundle branch block and ST segment elevation in the right precordial leads in the absence of long QT intervals and any structural heart disease. This syndrome is associated with an increased risk of sudden cardiac death due to malignant ventricular dysrhythmias [1]. Several clinical conditions and electrolyte imbalances, including hypokalemia, can provoke ECG changes and ventricular dysrhythmias in Brugada syndrome [2]. We present a case report of Brugada syndrome diagnosed after aborted sudden cardiac death due to hypokalemia caused by liquorice ingestion, a herbal product.

Case Report

A 50-year-old woman admitted to our emergency department with complaints of generalized weakness, chest pain and sweating for 4 h. Relatives of the patient stated that she had a syncopal attack 1 h before complaints of palpitation and dizziness, which she had never described before. She did not have any cardiovascular or systemic illness and was not taking any medication. She had no prior personal history of syncope or aborted cardiac arrest and her family history was also negative for sudden cardiac death. On admission, her pulse rate was regular with 64 beats/min, blood pressure was 170/100 mm Hg and her body temperature was 37.1 °C. She was confused, and physical examination was unremarkable.

except for a mild apical systolic murmur. ECG showed sinus rhythm, a ventricular rate of 112 beats/min and right bundle branch block. The corrected QT interval was 0.45 s, with a J point elevation of 2 mm and a PR interval of 0.22 s. Cranial computed tomography was taken to rule out a cerebrovascular accident, which revealed normal findings. Complete blood count and cardiac troponins were in normal limits, but blood biochemistry disclosed hypokalemia (1.77 mEq/l) and a mild disturbance in liver function tests (ALT 84.5 U/l, AST 102 U/l, GGT 78.8 U/l). The patient had neither a history of vomiting and diarrhea nor recent medication usage that might cause the electrolyte disturbance, except for a herbal product that contained liquorice. Detailed history revealed that she had been drinking 2 cups of liquorice extract a day for 3 months to relieve generalized weakness. During monitoring in the emergency department, ventricular fibrillation was witnessed and was successfully converted to sinus rhythm with a single shock of 300 J. Intravenous potassium replacement was started with 20 mEq/h and the control level was 2.65 mEq/l after 4 h. A 12-lead ECG taken 24 h after admission showed sinus rhythm with a coved-type ST segment elevation on precordial leads V1–V2 followed by a deep T-wave inversion; the serum potassium level at the time was 3.19 mEq/l (fig. 1). The corrected QT interval was 0.44 s, with a J point elevation of 1 mm in V1 and 2.5 mm in V2 and a PR interval of 0.22 s. Echocardiography showed mild mitral and tricuspid insufficiency with normal systolic function and right ventricular dimensions. Coronary angiography revealed normal coronary vessels. At 1 week, plasma K⁺ increased to 3.9 mEq/l and QRS further narrowed. With the recovery from hypokalemia, no dysrhythmia was recorded. Oral potassium replacement was given for 1 week and, after normal serum levels were reached, the patient was discharged from hospital uneventfully. After 3 months, the serum potassium level was 4.3 mEq/l after withholding liquorice ingestion without further potassium supplements. The corrected QT interval was 0.44 s, J point elevation was 1 mm in V1 and 2 mm in V2, and the PR interval was 0.22 s (fig. 2). Because the Brugada phenotype had appeared with accompanying hypokalemia, an intravenous ajmaline challenge

was performed 3 months later. Ajmaline at a dose of 1 mg/kg was administered over 5 min in the electrophysiology laboratory. The ajmaline challenge revealed a coved-type ST segment elevation in V1–V2 as well as a ventricular rate after 14 min (fig. 3). These results confirmed the diagnosis of Brugada syndrome and an implantable cardioverter defibrillator was implanted for secondary prevention of sudden cardiac death.

Discussion

A Brugada-like ECG pattern can be seen in several conditions other than Brugada syndrome like antiarrhythmic agents – such as flecainide, procainamide or ajmaline – physical stress, hypothermia and electrolyte disturbances like hypokalemia and hyperkalemia [2–4]. The present case highlights the effects of hypokalemia on the ECG of a patient diagnosed with Brugada syndrome. Brugada syndrome is characterized by ECG findings of apparent or real right bundle branch block and ST segment elevation in the right precordial leads with a high risk of ventricular tachycardia/ventricular fibrillation in the absence of structural heart disease, as described by Brugada and Brugada [5]. ECG findings may change over time and even normalization in ECG may be observed. The pathophysiologic mechanism underlying these ECG changes is an outward shift in the ionic current balance during the early phase 1 of the action potential causing a marked accentuation of the action potential notch, predominantly in the right ventricular epicardium [6].

Glycyrrhizic acid (GA) is the active molecule of liquorice which is converted to glucuronic acid and glycyrr-

retinic acid in the intestine, and plays a role in the inhibition of the enzyme 11- β -hydroxysteroid dehydrogenase type 2. As this enzyme catalyses the inactivation of cortisol to cortisone, potassium excretion in the cortical collecting duct is increased due to mineralocorticoid effects of cortisol, which is the result of liquorice ingestion [7]. Sigurdsson et al. [8] stated that liquorice intake of 100 g/day, which contains 150 mg of GA, causes an increase in systolic blood pressure of 15 mm Hg in hypertensive patients and of 3.5 mm Hg in normotensive subjects. Although a dose-response relation between GA amount and cortisol-cortisone ratio was shown by Krähenbühl et al. [9], there were also case reports [10] describing clinical effects due to

low-dose liquorice intake. The mechanism of susceptibility to the effects of GA is not clear, but a mechanism was described regarding the tendency for females, considering the effects of estrogens on mineralocorticoid receptors [11].

In this patient, liquorice-induced hypokalemia was suspected to provoke the ECG changes and ventricular fibrillation. Also, hypertension was thought to be the result of liquorice ingestion as the patient remained normotensive after cessation of liquorice extract. Cardiac arrest due to hypokalemia-induced ventricular fibrillation related to QT prolongation was reported previously [12]. However, in this case, only a small increase in corrected QT interval and PR interval was observed in our patient.

Fig. 3. ECG taken at the end of the ajmaline challenge test showing coved-type ST segment elevation in V1–V2 (arrows).

These findings may be due to a loss of function mutation in SCN5A gene, which is often observed in Brugada syndrome patients manifesting first-degree atrioventricular block, as in our patient. Coved-type ST segment elevation was reduced with potassium replacement suggesting that hypokalemia contributed to the induction of ventricular fibrillation via a Brugada syndrome mechanism, rather than an acquired long QT mechanisms. Araki et al. [2] and Notarstefano et al. [13] reported cases with ventricular dysrhythmias and described the role of hypokalemia as the suggested mechanism in the occurrence of ventricular tachycardia and fibrillation in Brugada syndrome. The ECG changes may vary over time in a dynamic manner in Brugada syndrome, as in our case report.

Conclusion

In the present case, a rare case of hypokalemia was caused by liquorice ingestion, a herbal product, and provocation of ventricular fibrillation in an asymptomatic patient with Brugada syndrome. This report highlights the importance of investigating herbal medications in the detailed history of a patient in the cases of electrolyte disturbances and the potential role of hypokalemia for the induction of malignant dysrhythmias in Brugada syndrome.
