Key Words

Sclerosing peritonitis · Abdominal cocoon · Bowel obstruction

Abstract

Sclerosing peritonitis, more commonly called abdominal cocoon, is a rare intra-peritoneal disease that is characterized by complete or partial encapsulation of the small intestine by a thick collagenous membrane. This disease mostly presents in the form of small bowel obstruction, however in our case the patient presented with intra-cocoon bleeding following a motor vehicle accident.

Introduction

Sclerosing peritonitis has many different names with no consensus for the ideal syndrome name. It is also called peritonitis fibrosa incapsulata or abdominal cocoon and was originally described in 1907 as a membranous encapsulation of the small intestine [1]. It was then further investigated and a detailed description was made by Foo et al. in 1978 [2]. Most of what has been published are case reports since this disease is rare. According to the literature, this disease presents most commonly with small bowel obstruction in the form of either complete or partial obstruction [3]. We report a rare presentation of this disease in the form of bleeding from the wall itself following a motor vehicle accident.

Case Report

A 37-year-old male presented to our emergency department as the victim of a road traffic accident with blunt abdominal trauma and generalized abdominal pain. Primary survey was within normal with stable vital signs. Abdominal examination showed a distended abdomen with generalized tenderness. Hemoglobin level on presentation was 13.6 g/dl. Emergency computed tomography of the abdomen and pelvis was done and revealed small hemoperitoneum and a loculated hematoma within a sac containing the small bowel as shown in [figure 1](#).

The patient was admitted to the male surgical ward for observation and conservative management. About one hour after admission he started to be drowsy and his blood pressure dropped from 119/87 mm Hg at admission to 74/47 mm Hg and he became tachycardic. Abdominal examination showed distended abdomen with generalized tenderness and generalized rebound tenderness. Hemoglobin and hematocrit levels dropped markedly from 13.6 g/dl and 42.3% to 10.5 g/dl and 32.1%, respectively.

Emergent exploratory laparotomy was performed. Operative findings were as follows: a large cyst containing the whole small bowel from the duodenojejunal flexure down to the ileocecal junction, with massive hemorrhage into it, along with a small amount of blood around the liver, spleen and pelvis ([fig. 2](#)). The cyst was opened up and a large amount of blood clots was evacuated. A deep through and through radial mesenteric tear from the root of the mesentery down to the wall of the ileum was seen with no evidence of bowel ischemia. Bleeding was controlled and the tear was closed. Excision of the cyst along with partial omentectomy was done and homeostasis was maintained. Postoperatively he recovered well, with an uneventful hospital stay. Histopathological examination of the abdominal, omental and mesenteric tissues showed a cystic wall lined by low cuboidal mesothelial cells composed of congested fibrofatty and collagenous tissue.

Discussion

As previously mentioned, abdominal cocoon is a rare disease described by Foo et al. in 1978 [2]. Subsequently many case reports have described its presentation, pathogenesis, prognosis and radiological manifestations. Most descriptions in the literature showed a high prevalence of small bowel obstruction in these patients who are usually young, middle-aged and living in tropical areas [3]. Other reports described an asymptomatic abdominal mass or an accidental radiological or intra-operative finding. In our report we present a case with intra-cocoon hemorrhage due to mesenteric tear within the cocoon caused by blunt abdominal wall trauma in a motor vehicle accident. The question we asked ourselves was whether such a condition predisposes patients to have easily an injury of the mesentery due to the short mesentery and the presence of the cocoon.

Radiological manifestations are challenging to be concluded as an intra-abdominal cocoon, however Sieck et al. described the presence of cauliflower sign on a contrast small intestine study [4], and Maguire et al. described the delay of passage of contrast to be more common and diagnostic than the cauliflower sign [5]. Wig and Gupta described the presence of a membrane around a cluster of small intestine [6]. Clatworthy et al. described the calcified abdominal cocoon to be more common secondary to peritoneal dialysis [7].

The pathogenesis of this disease is unknown and poorly understood. Hsu et al. [8] categorized it in two groups: peritoneal dialysis-dependent and peritoneal dialysis-independent intra-abdominal cocoon. Peritoneal dialysis-dependent is probably related to the duration of peritoneal dialysis, repetitive infection, acidity of the solution, high osmolarity and sterilizing agent such as chlorhexidine. Peritoneal dialysis-independent factors include beta blockers and genetic predisposition or developmental in the form of omental dysplasia [3].

The treatment of intra-abdominal cocoon is adhesolysis and excision of the fibrotic membrane. The procedure should be done adequately in order to decrease the recurrence of small bowel obstruction. Most of the cases described were managed with a laparotomy incision, however others were successfully treated with minimally invasive surgery [9].

To prevent extensive adhesion, which may lead to the recurrence of small bowel obstruction in 12%, it is suggested to rinse the peritoneal cavity with an adherent such as sodium hyaluronate or hydrocortisone and to relieve postoperative ileus with early ambulation and mosapride administration.

Conclusion

Abdominal cocoon is a rare disease. We present a case with intra-cocoon bleeding following a motor vehicle accident. The publication of this article aims at raising the awareness of this disease and possibly the increased incidence of mesenteric tear after blunt abdominal wall trauma in patients with this disease. Treatment is still surgical exploration even if the patient's condition is stable to prevent extensive adhesion formation from the intra-cocoon blood and thus decrease the incidence of small bowel obstruction which presents commonly in this disease.
