Key Words

Cystoid macular edema · Irvine-Gass syndrome · Dexamethasone 0.7 mg · Ozurdex®

Abstract

Purpose: To report the effective treatment of cystoid macular edema (CME) following complicated cataract surgery (resulting in Irvine-Gass syndrome) with a dexamethasone 0.7-mg (Ozurdex®) intravitreal implant.

Methods: An interventional case report with optical coherence tomography (OCT) scans.

Results: An 83-year-old Caucasian woman was suffering from CME following complicated cataract surgery on her left eye. She had undergone 3 intravitreal injections of dexamethasone 0.4 mg in the 3 months following the surgery without any improvement of visual function. Seven months after the cataract surgery, she received a single intravitreal injection of dexamethasone 0.7 mg (Ozurdex). Four weeks following the injection, her best-corrected visual acuity improved from 0.3 to 0.8. CME resolved with a reduction of central retinal thickness from 393 µm pre-Ozurdex injection to 212 µm post-Ozurdex injection, as measured by OCT scan.

Conclusion: Dexamethasone 0.7 mg (Ozurdex) has proven to be an effective treatment option in retinal vein occlusion and non-infectious uveitis. It can also be considered as off-label treatment in Irvine-Gass syndrome.

Introduction

Irvine-Gass syndrome, which describes vision loss after cataract surgery due to cystoid macular edema (CME), is still recognized as one of the most common causes of poor visual outcome following cataract surgery [1, 2]. Despite treatment options for Irvine-Gass syndrome which include non-steroidal anti-inflammatory drugs, corticosteroids and

acetazolamide, and new fields of clinical research including the use of anti-vascular endothelial growth factor agents, resistant cases of macular edema are common [3, 4].

Corticosteroids are potent anti-inflammatory agents that can counteract many of the pathological processes thought to play a role in the development of postoperative CME. Recently, a sustained-release dexamethasone implant (Ozurdex®) has become available for the treatment of patients suffering from CME due to retinal vein occlusion and non-infectious uveitis [5].

We report a case of CME resolution and significant improvement of visual function following the intravitreal injection of dexamethasone 0.7 mg in a patient with Irvine-Gass syndrome even after previous intravitreal therapy with dexamethasone 0.4 mg had been repeatedly unsuccessful.

Case Report

An 83-year-old Caucasian woman developed CME following complicated cataract surgery on her left eye in 2010 (fig. 1). She had undergone 3 intravitreal injections of dexamethasone 0.4 mg in the following 3 months without any improvement in visual acuity. Seven months after the cataract surgery, she presented for the first time at our clinic and received a single intravitreal injection of dexamethasone 0.7 mg (Ozurdex) as off-label treatment. Four weeks following the injection, her best-corrected visual acuity (BCVA) improved from 0.3 to 0.8. The CME resolved with a reduction of central retinal thickness from 393 μ m pre-Ozurdex injection to 212 μ m post-Ozurdex injection, as measured by optical coherence tomography (OCT) scan (fig. 2). Her condition has been stable for at least 3 months now, as seen on the last examination, with BCVA 0.8 and resolved macular edema (fig. 3) in the treated eye.

Discussion

Current evidence suggests that the dexamethasone 0.7-mg implant (Ozurdex) is a favorable treatment option in patients with CME and vision loss due to retinal vein occlusion and non-infectious uveitis [6, 7]. In accordance with the case report presented here, a subgroup analysis of a clinical phase II study indicated that dexamethasone 0.7 mg might also be effective in patients suffering from Irvine-Gass syndrome following cataract surgery [8].

However, it is unknown whether the dexamethasone 0.7-mg implant could even effectively reduce CME in already pre-treated eyes that were refractory to previous intravitreal dexamethasone injections. Our case report indicates that Ozurdex effectively restores visual function and reduces CME in Irvine-Gass syndrome even though previously applied intravitreal treatment with 3 dexamethasone injections was unsuccessful. Similar to the results from Williams et al. [8], who reported a considerable functional improvement after treating Irvine-Gass patients with dexamethasone 0.7 mg, our patient improved from BCVA 0.3 pre-Ozurdex injection to BCVA 0.8 post-Ozurdex injection.

A possible explanation for the inefficiency of previous intravitreal dexamethasone injections in the presented case could be the short half-life of unbound dexamethasone in the vitreous cavity [9]. This problem can be overcome by the currently available sustained-release dexamethasone implant.

In conclusion, the dexamethasone implant (Ozurdex) might be an effective treatment option not only in retinal vein occlusion and non-infectious uveitis but can also be considered as off-label treatment in Irvine-Gass syndrome.
