Carpenter syndrome • GTPase • Mutation • Prenylation • *RAB23*

Abstract

Carpenter syndrome is caused by mutations in the *RAB23* gene that encodes a small GTPase of the Rab subfamily of proteins. Rab proteins are known to be involved in the regulation of cellular trafficking and signal transduction. Currently, only few mutations in *RAB23* have been reported in patients with Carpenter syndrome. In this paper, we report the clinical features, molecular and functional analysis of 2 children from an Emirati consanguineous family with this syndrome. The affected children exhibit the typical features including craniosynostosis, typical facial appearance, polysyndactyly, and obesity. Molecular analysis of the *RAB23* gene revealed a homozygous mutation affecting the first nucleotide of the acceptor splice site of exon 5 (c.482-1G>A). This mutation affects the authentic mRNA splicing and activates a cryptic acceptor site within exon 5. Thus, the erroneous splicing results in an eight nucleotide deletion, followed by a frameshift and premature termination codon at position 161 (p.V161fsX3). Due to the loss of the C-terminally prenylatable cysteine residue, the truncated protein will probably fail to associate with the target cellular membranes due to the

absence of the necessary lipid modification. The p.V161fsX3 extends the spectrum of *RAB23* mutations and points to the crucial role of prenylation in the pathogenesis of Carpenter syndrome within this family.

Carpenter syndrome (MIM 201000) is a rare autosomal recessive pleiotropic disorder characterized by combination of acrocephaly, brachydactyly and syndactyly in the hands as well as preaxial polydactyly and syndactyly of the toes. Other variable features include obesity, mental retardation and hypogonadism [Carpenter, 1909; Temtamy, 1966; Robinson et al., 1985; Cohen et al., 1987]. It has an incidence of 1 in a million live births (<http://rare-diseases.about.com/od/acps/a/carpenter.htm>). The most common and evident physical manifestation at birth is acrocephaly due to early fusion of the cranial sutures. Facial abnormalities include flat nasal bridge, broad cheeks and malformed and unevenly set ears. In addition, it includes a wide upturned nose with abnormally large nares and usually late eruption of small and widely spaced teeth.

S. Ben-Salem and M.A. Begum contributed equally to this work.

Mild mental retardation is present in 75% of affected children, and roughly half of them are born with some types of heart defects [Frias et al., 1978; Perlyn and Marsh, 2008] (<http://www.rarediseases.org/rare-disease-information/rare-diseases/byID/612/viewAbstract>).

Using homozygosity mapping, Jenkins et al. [2007] mapped the gene for this syndrome to chromosome 6p12.1q12 and identified several mutations in the *RAB23* gene. This gene consists of 1 noncoding and 6 coding exons, spanning a region of 35.43 kb, which encodes a small GTPase protein belonging to the Ras superfamily. This protein plays an essential regulator role in the sonic hedgehog signaling pathway and vesicular trafficking [Jenkins et al., 2007]. Rab23 has been identified earlier to act as a negative regulator of sonic hedgehog signaling [Eggenschwiler et al., 2006]. More recently, Boehlke et al. [2010] showed that Rab23 is involved in the protein turnover within the cilium by increasing the recycling of Smo, a downstream effector smoothened, in the sonic hedgehog signaling pathway.

To date, 11 mutations have been reported in the *RAB23* gene responsible for Carpenter syndrome [Jenkins et al., 2007; Alessandri et al., 2010; Jenkins et al., 2011]. In the present study, we report the identification of a novel splicing mutation (c.482-1G>A) in the *RAB23* gene causing Carpenter syndrome in a consanguineous Emirati family. This mutation abolished the acceptor splice site of exon 5, which led to an eight nucleotide deletion in the *RAB23* mRNA followed by a stop codon.

Subjects and Methods

Subjects

Blood samples were collected from the 2 affected children, parents and one unaffected sibling.

Mutation Screening

To identify the mutation(s) causing this syndrome, PCR amplification of the 6 coding exons of the *RAB23* gene were performed on 2720 thermal cycler (Applied Biosystems, USA). Primers were designed using Primer3 software version 0.4.0 (<http://frodo.wi.mit.edu/>) (online suppl. table 1, for all supplementary material see www.karger.com/doi/10.1159/000345653). A total volume of 20 µl of PCR reactions were prepared containing 1× PCR buffers (Qiagen GmbH, Germany), 0.2 mM dNTPs, 5 µM of each forward and reverse primers, 100 ng of template DNA, and 0.5 U Taq DNA polymerase (Qiagen GmbH). The PCR products were purified using ExoSAP-IT (USB Inc.) followed by DNA Sanger cycle sequencing using the BigDye Terminator kit v3.1 (Applied Biosystems) and were run on the 3130xl Genetic Analyzer System (Applied Biosystems). The results were analyzed using Sequencing Analysis® 5.3 software (Applied Biosystems).

In silico Prediction of the Cryptic Splice Site Mutation c.482-1G>A

To evaluate the potential influence of c.482-1G>A mutation on splicing signals, *in silico* prediction was carried out using the scan program (<https://splice.uwo.ca/>) [Schneider, 1997a, b] along with the Human Splicing Finder software version 2.4.1 (<http://www.umd.be/HSF/>) [Desmet et al., 2009]. The prediction was performed based on the following reference sequence: ENST00000317483 transcript.

Effect of c.482-1G>A Mutation on mRNA Splicing

To elucidate the effect of this mutation, total RNA was extracted from blood using QiAamp RNA isolation Mini kit (Qiagen GmbH). The cDNA was prepared by reverse transcription (RT-PCR) using Omni Script RT kit (Qiagen GmbH) according to the manufacturer's instructions. A PCR amplification of *RAB23* cDNA was performed in patient IV-2 and control samples. PCR products were purified, followed by Sanger cycle sequencing reactions and screened by 3130xl automated sequencer (Applied Biosystems).

Relative Quantification of *RAB23* mRNA Transcripts

The expression levels of *RAB23* mRNA were analyzed in one affected (IV-2), carrier (III-1) and healthy control samples using TaqMan assays using the 7500 Real Time PCR system (Applied Biosystems). *GAPDH* was used as an internal control, and all experiments were run in duplicates. A 270 bp *RAB23* product, spanning exon 1 and exon 3 (primers listed in online suppl. table 1), was amplified and quantified in a total volume of 25 µl containing 12.5 µl of 2X TaqMan gene expression Master Mix (Applied Biosystems), 0.5 µl of each forward and reverse primers, 0.625 µl of fluorescent probe, and 2 µl of the cDNA samples. The amplification condition is as following: 10 min activation at 95°C, followed by 40 cycles amplification for 95°C for 45 s and 57°C for 45 s. Data analysis was performed using 7500 System Software (Applied Biosystems).

Ethics Statement

This study has been approved by Al-Ain Medical Human Research Ethics Committee according to the national regulations (protocol number 10/09). The parents of the patients provided an informed written consent form prior to research, publication and agreed to use the photographs of their children for medical publication.

Results

Clinical Description

The parents are first cousins of United Arab Emirates origin and have 4 children (fig. 1). Two of the children are affected by Carpenter syndrome.

The first child (IV-1) was the product of normal pregnancy. Prenatal ultrasound showed abnormal head shape, and, therefore, the baby was delivered by low cesarean section at 38 weeks. His birth weight was 4,080 g (>90%), length 48 cm (<50%) and head circumference 37 cm

Fig. 1. Pedigree of Emirati family with Carpenter syndrome. Pedigree shows the Emirati family with 2 patients with Carpenter syndrome. Circles and squares denote females and males, respectively; filled symbols represent affected members; double lines denote consanguineous marriage. Arabic numbers represent tested individuals; Roman numbers indicate the first generation until their offspring.

(>90%). The Apgar scores were 8 and 9 at 1 and 5 min, respectively. Clinical examination revealed acrocephaly with closed anterior fontanelle, upward slanting of the palpebral fissures, prominent eyes, and depressed nasal bridge with low set ears. The boy also had brachydactyly with contractures of the proximal interphalangeal joints and complete cutaneous syndactyly between 3rd and 4th fingers bilaterally (fig. 2A). There was preaxial polydactyly of both feet and syndactyly of all the other toes. There was bilateral metatarsus varus (fig. 2B). Cranial CT scan confirmed the presence of synostosis of all sutures. There was dilatation of the lateral ventricles. Ophthalmological examination was normal. Craniosynostosis was operated on successfully. This child is 7 years old now and has mild developmental delay. He is attending school and is at the appropriate grade level; however, he needs extra help.

The second child (IV-2) was a girl of normal pregnancy. Prenatal ultrasound at the third trimester showed immobile fingers and abnormal skull shape. Delivery was by low cesarean section. Her birth weight was 3,375 g (50%), length 45 cm (<3%) and head circumference 36 cm (90%). At birth, she was noted to have clover-leaf appearance of the cranium with all sutures; the anterior and posterior fontanelles were closed. The eyes were prominent, furthermore there was a depressed nasal bridge, high arched palate and low set ears (fig. 2C). She also had cutaneous syndactyly and brachydactyly of all fingers of both hands with limited extension of the proximal interphalangeal joints of

all fingers (fig. 2D) as well as bilateral preaxial polydactyly of feet and cutaneous syndactyly of all toes. Cranial CT scan showed closure of all sutures, with absence of bone structure in the temporal-parietal region on both sides. Moreover, the affected child also had dilatation of the lateral ventricles which required a ventriculo-peritoneal shunt. Hand X-rays showed absence of the middle phalanges of all the fingers. Craniosynostosis was operated on successfully at the age of 3 months. She is 6 years old now and has mild delay in speech. She is attending school and she is in the appropriate grade level.

Identification of G to A Substitution in the First Nucleotide of the Acceptor Splicing Site of Exon 5

DNA sequencing of *RAB23* identified a homozygous c.482-1G>A substitution affecting the first nucleotide of the acceptor splicing site of exon 5 (fig. 3A). This novel mutation segregated well with the phenotype in the studied family (fig. 3B). Only the affected individuals (IV-1 and IV-2) were homozygous for this mutation, while the parents (III-1 and III-2) and the child VI-3 were carriers for this mutation.

Computational Analysis of the c.482-1G>A Effect on Splicing

Several studies have shed light on the role of the splice site variants that are disease causing. Mutations affecting the highly conserved sequences of the acceptor and donor splice sites were expected to cause splicing aberrations [Burset et al., 2000]. Both computational studies used in the present study predicted the loss of the canonical acceptor splice site and the activation of cryptic splice site 8 nucleotides upstream of exon 5. The c.482-1G>A mutation is expected to cause the deletion of TTTTAAAG at the beginning of exon 5, leading to a frameshift and thus, creating a stop codon (online suppl. fig. 1 and suppl. table 2).

*Sanger Sequencing of the *RAB23* cDNA*

Bidirectional sequencing of *RAB23* transcripts were performed in one of the patients (IV-2) and healthy control samples. Analysis of the chromatograms, as shown in figure 3C, confirmed the presence of the deletion of 8 nucleotides (TTTTTAAAG) at the beginning of exon 5. The out-of-frame sequences would allow the translation of only 3 amino acids (p.V161fsX3) in exon 5 before encountering a stop codon (fig. 3).

*Quantitative Expression of *RAB23* Transcripts*

Relative quantification of *RAB23* mRNA was carried out in cDNA samples from one affected (IV-2), one car-

Note acrocephaly, upslanting palpebral fissures, wide nasal bridge and tip, and polysyndactyly of the toes. **B** Appearance of the hand at birth in patient IV-1 showing syndactyly of the fingers. **C** Appearance of patient IV-2 at 6 years. The craniosynostosis has been operated on. Note prominent metopic ridge, widely spaced eyes with epicanthic folds and depressed nasal bridge. **D** Appearance of the hand in patient IV-2. Note brachydactyly and scar of the operation for syndactyly.

rier (III-1) and a healthy individual using qReal-Time PCR. Data analysis showed no significant difference in the level of expression of *RAB23* mRNA between the 3 studied samples normalized to an internal control *GAPDH* (online suppl. fig. 2).

Discussion

We report here the identification of a novel mutation in the *RAB23* gene in a consanguineous family from the United Arab Emirates. The 2 affected siblings had the typical features of Carpenter syndrome. There was no intrafamilial phenotypic variability in this family. Both had craniosynostosis leading to acrocephaly with clover-leaf shape of the skull in one of them. There was brachydactyly with absence of the middle phalanges and syndactyly of the hands, with preaxial polydactyly and syndactyly of the toes in both children. Both had high birth weight, developed obesity in childhood and had mild developmental delay. Carpenter syndrome is known to be clinically heterogeneous, in particular, the severity of craniosynostosis, mental retardation and obesity with high birth weight. However, molecular studies have shown that at the molecular level it is a homogenous condition [Jenkins et al., 2007, 2011; Alessandri et al., 2010].

All Rab proteins display a similar distribution within their functional domains. Rab23 proteins encompasses 4 GTP/GDP pockets, 2 'switch' domains interacting with the Rab effector proteins, which experience conformational changes based on the presence of either GDP or GTP. In addition, it comprises a magnesium binding residue as well as cysteine residues in the C-terminus which is subjected to prenylation. Cysteine residues undergo lipid modification followed by geranylgeranylation during post regulation. This step is crucial for the activation and targeting of Rabs proteins to their specific membrane [Ali and Seabra, 2005; Ali et al., 2010; Jenkins et al., 2011]. Rab13 and 23 represent an exception, since they contain only a single cysteine residue in their C-terminal compare to other Rabs proteins. This single cysteine distinguishes Rab23 by allowing it to escape from trafficking and pass through the secretory pathway [Leung et al., 2007]. So far, the contribution of different *RAB23* domains in the pathogenesis of Carpenter syndrome is not well understood [Jenkins et al., 2011].

To date, 30% of the inherited genetic disorders and different forms of cancer are modulated by nonsense-mediated decay (NMD) due to frameshifts or nonsense point mutations [Frischmeyer and Dietz, 1999; Khajavi et al., 2006]. The c.482-1G>A is the first homozygous splice site mutation described affecting the 3' end of *RAB23*. This

Fig. 3. Schematic representation of *RAB23* and molecular analysis of c.482-1G>A on splicing and protein translation. **A** Top: genomic organization of exons and introns of *RAB23*. Middle: wild-type pre-mRNA representation and functional domain in the 237 amino acid protein. Bottom: the truncated pre-mRNA and mutant protein. **B** Chromatograms of healthy control, homozygous and heterozygous individuals, respectively. Chromatograms show a novel substitution of G to A in the acceptor splice site of exon 5 (c.482-1G>A) depicted by a small arrow. The

beginning of exon 5 is underlined. **C** Chromatograms of cDNA sequence analysis from patient (IV-2) and healthy control. The substitution alters the 3' consensus splice site and activates a cryptic acceptor splice site downstream in exon 5 at position c.490. This results in the deletion of 8 nucleotides from the beginning of exon 5, causing a frameshift followed by a premature termination codon. X = Represents the premature termination codon. Nucleotide sequences of exon 4 and 5 are underlined.

Table 1. Summary of *RAB23* mutations identified in patients with Carpenter syndrome

Exons	DNA	Protein	Country/region of origin	References

The numeration of exons was restricted to the coding exons only. The numbering for the nucleotide and protein changes are based on cDNA sequence in accordance with the GenBank entries NM_183227.1 and NP_899050.1. ins = Insertion; dup = duplication; del = deletion.

mutation led to a frameshift which would allow the translation of only 3 amino acids of exon 5 before encountering a stop codon. Thus, the truncated proteins, if produced, will lack 76 amino acids in their C-terminus (fig. 2C). From a total number of 11 mutations, reported to date in the *RAB23* gene, 8 nonsense mutations have been identified (table 1) [Jenkins et al., 2007, 2011; Alessandri et al., 2010]. Accordingly, the truncation mutations are the major cause of Carpenter syndrome due to the loss of function of *RAB23* proteins. Screening a total of 10 unrelated families of Northern Europe origin with Carpenter syndrome revealed the presence of one mutation (c.434T>A (p.L145X)), suggesting a founder effect [Jenkins et al., 2007, 2011]. Functional analysis has demonstrated that the nonsense p.L145X mutation encodes transcripts which undergo NMD [Jenkins et al., 2011]. To investigate whether the c.482-1G>A will produce truncated transcripts subject to NMD, we performed a quantitative expression of *RAB23* mRNA. Notably, relative quantification of *RAB23* transcripts showed no significant difference in the level of expression of *RAB23* mRNA in patient (IV-2), carrier (III-1) and control samples using TaqMan assays (online suppl. fig. 2). Thus, the c.482-1G>A mutation will give rise most probably to a stable truncated mRNA, since the position of this mutation is very close to the end of *RAB23* transcript. Consequently, the mRNAs most likely escape from the NMD survey of the cell. As a result, the truncated protein will probably be mislocalized within the cell due to the lack of its lipid modifica-

tions. Subsequently, the mutation leads to loss of its biological function(s) which explains the pathogenicity of this mutation in this family. This finding highlights the crucial role of lipid modification as alternative machinery of cellular control and is a vital step for the targeting of functional *RAB23* proteins.

In conclusion, we show that the c.482-1G>A splice site mutation, found in the *RAB23* gene, is responsible for the typical features of Carpenter syndrome in a consanguineous Emirati family. Molecular and bioinformatics analyses revealed that the single base substitution led to an activation of cryptic splice site downstream in exon 5. The truncated transcripts produced nonfunctional proteins due to loss of lipid modification. This finding extends the spectrum of *RAB23* mutations and highlights the important role of this gene as major cause of Carpenter syndrome worldwide. Finding disease causing mutations of recessive disorders is crucial for adopting effective prevention strategies, especially in highly consanguineous populations like the United Arab Emirates [Al-Gazali and Ali, 2010].
