Neutrophils in the Innate Immunity Conundrum of Cystic Fibrosis: A CFTR-Related Matter?

Until recently, the main focus of cystic fibrosis has been the function of the CFTR (cystic fibrosis transmembrane regulator) channel in epithelial cells. We know that its failure leads to airway epithelium dehydration, thick mucus accumulation and impaired mucociliary clearance, the hypothesis being that this allows bacterial trapping, resulting in chronic lung infections [1]. However, more than 2 decades after the CFTR cloning, we still do not understand how it relates to lung disease and to the tremendous neutrophil burden that persists within the airways nor why chronic colonization with *Pseudomonas aeruginosa* develops in cystic fibrosis patients who are supposed to be immunocompetent. Although a general defect in innate immunity is now mooted [1], the question remains: Why don't neutrophils do a better job?

In this issue, Zhou et al. [2] examine phagosomal targeting of CFTR in neutrophils and the impact of the $\Delta F508$ mutation on this process. Previous studies from this group have already provided evidence that CFTR channel expression in neutrophils and its dysfunction can affect neutrophil chlorination of phagocytosed bacteria [3] and that CFTR-dependent chloride anion transport contributes significantly to *P. aeruginosa* killing by normal neutrophils [4]. The presence of CFTR in neutrophils has remained controversial for years. Its detection has

been challenging because of the lack of reliable anti-CFTR antibodies and the low amount of CFTR present in neutrophils. In the current study, Zhou et al. [2] used CFTR-stably transfected PLB985 cells to demonstrate that the $\Delta F508$ -mutated CFTR failed to localize in phagosomes. Notably, this was rescued by the CFTR corrector compound VRT-325, thus strongly suggesting that a therapeutic strategy aimed at restoring full CFTR function [5] might also target neutrophils.

One unsolved debate still remains as to whether the dysregulation of innate immunity in cystic fibrosis is acquired or constitutive. Unfortunately, no current animal model (neither mice nor ferrets nor pigs) can accurately mimic the lung disease observed in patients with cystic fibrosis. Nevertheless, some studies have reported that neutrophils from mice expressing the $\Delta F508$ CFTR or mice lacking CFTR in myeloid cells have a proinflammatory phenotype after lipopolysaccharide [7] or bacterial [8] challenge thus suggesting that CFTR expression in neutrophils might regulate their function. Since neutrophils are the major cell type and their accumulation is associated with lung failure, it is reasonable to meticulously scrutinize them in cystic fibrosis. The study of heterozygous individuals could provide a unique opportunity to uncover constitutive disturbance, independently of infec-

tions, and thus provide some insight into this debate [9]. Previous studies have shown that neutrophils from heterozygous individuals have increased oxidant production [10] as well as a delayed apoptosis [11], thus presumably potentiating their proinflammatory capacity. Interestingly, the delayed apoptosis observed in neutrophils from cystic fibrosis patients and from their parents was not reversed by an inhibitor of CFTR compared with controls, which strongly suggests that CFTR functions in neutrophils may be independent of its chloride channel function. This concept of channel-independent functions is no longer in doubt given the multiplicity of proteins with various functions that have been shown to be associated with CFTR [12].

A number of significant experiments have underscored the importance of neutrophils in innate immunity and their functions appear to extend far beyond their

well-described, essential role in antibacterial defense. Thus, one can postulate that a disturbance in neutrophil reprogramming would severely impair the course of an inflammatory challenge. Both the image we have of neutrophils and the immunological conundrum posed by cystic fibrosis have evolved but the troubling question of the role of neutrophils in cystic fibrosis remains [13]. The work of Zhou et al. [2] supports the possibility that the CFTR may be important for human neutrophils to fully achieve their bactericidal capacity. This report is timely, as we urgently need to understand the impact of neutrophil function/dysfunction in cystic fibrosis and how it relates to the CFTR. Moving on from the conventions of the last decade regarding neutrophil functions, this hypothesis of a constitutive disturbance of neutrophils in cystic fibrosis may allow for a true working paradigm with therapeutic implications for today.
