Brunner's gland hamartoma · Hematemesis · Melena · Endoscopic mucosal resection

Abstract

Brunner's gland hamartoma is a rare benign small bowel neoplasm and most lesions are small and asymptomatic. However, large hamartoma-related obstructive symptoms and hemorrhage related to tumor ulceration manifest as hematemesis or melena. The exact pathogenesis of these lesions is not well known, but they are thought to be frequently associated with *Helicobacter pylori* infections and chronic pancreatitis. We report the case of a 45-year-old man who presented with melena due to a large pedunculated Brunner's gland hamartoma arising from the pylorus. It was successfully removed by endoscopic mucosal resection with piecemeal technique because of too large tumor size for application of a conventional snare.

Introduction

Benign small bowel neoplasms are uncommonly encountered. Brunner's gland hamartoma represent 5–10% of small bowel tumors and occurs most commonly in the fifth and sixth decade of life, with no gender or race predominance. Most of the lesions are small, asymptomatic and detected incidentally [1, 2]. Clinical symptoms are caused by obstruction, leading to postprandial pain, and bleeding. The location of the lesion is often at the bulb of the duodenum and the incidence decreases with increasing distance from the pyloric ring

[3]. In symptomatic patients, Brunner's gland hamartoma can be treated either by endoscopic or surgical excision [4]. We report a case of successful endoscopic removal of a large Brunner's gland hamartoma with gastrointestinal bleeding arising from the pylorus.

Case Report

A 45-year-old man presented with a 4- or 5-day history of melena. He also presented nausea lasting for 10 days. His medical history was not significant for hypertension or diabetes. On physical examination, he was afebrile with normal vital signs. His abdomen was soft and nontender. Laboratory tests showed his hemoglobin to be 10.2 g/dl. Esophagogastroduodenoscopy showed a pedunculated ulcerated mass about 50 mm large arising from the pyloric ring (fig. 1). We tried to pull the tumor into the stomach with a snare to prevent loss of the tumor after resection because the tumor head was located in the bulb of the duodenum. However, the tumor was too big to pass the pyloric ring. Therefore, endoscopic piecemeal mucosal resection was performed in the bulb of the duodenum for pulling out the specimen after resection; it was successfully removed by snare. A snare polypectomy was performed and secured with a clip. The lesion was a well-circumscribed mass of 48 × 32 mm, with an ulcerated surface and yellowish core (fig. 2). Histological examination of the mass showed Brunner's glands with ducts separated by fibromuscular stroma (fig. 3). After 5 months, follow-up esophagogastroduodenoscopy was performed; there was no evidence of recurrence.

Discussion

Brunner's glands were first described by Brunner in 1688 [5]. They are branched acinotubular glands located in the submucosa and lined with cuboidal-to-columnar clear cells in the glands and cuboidal cells in the duct [6]. The distinction between Brunner's gland hyperplasia and Brunner's gland hamartomas is arbitrary. Brunner's gland hyperplasia is considered if the lesion is <5 mm in size, either solitary or multiple, and Brunner's gland hyperplasia if it is >5 mm, contrary to Brunner's gland hyperplasia [7]. The symptomatic features of Brunner's gland hamartoma can be divided into two categories, namely hemorrhagic and obstructive type. The hemorrhagic manifestations due to ulceration or erosion of the tumor are melena, fatigue, anemia and rarely hematemesis [8]. Obstruction occurs when the hyperplasia is diffuse or a single adenoma grows too large, causing epigastric bloating, pain, nausea, vomiting and weight loss [9]. Patients with tumor-related obstructive complications tend to have hamartomas >2 cm [10]. In our case, the size of tumor was about 5 cm. The patient presented hemorrhagic manifestation such as 4 or 5 days of melena and obstruction symptoms like nausea. Uncommon presentations include obstructive jaundice, biliary fistula, recurrent pancreatitis or intussusception [5]. Most Brunner's gland hamartomas are located in the duodenal bulb (57%), but they may also be found in the second (27%) or third (7%) parts of the duodenum and are rarely detected in the pyloric canal (5%), jejunum (2%) or proximal ileum (2%) [2]. Most tumors are 1–2 cm in size, however, tumors sized about 9 cm are also reported [11]. In our case the tumor was originated from the pylorus, which seemed to be a rare location, and the size was bigger than usual.

The exact pathogenesis is not well known, but many etiologies were proposed for the pathogenesis of Brunner's gland tumors, such as local irritation, parasympathetic activity, chronic pancreatitis, *Helicobacter pylori* infection and Billroth II reconstruction [12]. An

Jung et al.: Successful Endoscopic Resection of Large Pedunculated Brunner's Gland Hamartoma Causing Gastrointestinal Bleeding Arising from the Pylorus

accurate diagnosis can be difficult. The differential diagnosis usually includes leiomyomas, adenomas, lipomas, Peutz-Jeghers syndrome, adenocarcinomas, carcinoids, lymphomas, leiomyosarcomas, pancreatic or ampullary neoplasm [13].

Asymptomatic small Brunner gland hamartomas usually require no treatment. However, treatment is suggested for larger tumors, even if asymptomatic, to prevent development of complications such as bleeding or obstruction. Endoscopic resection is the treatment of choice if the tumor is pedunculated and relatively small, whereas larger-sized lesions require open surgical resection. Recurrence after endoscopic or surgical excision has not been reported. In our case, we decided to resect endoscopically because of melena, obstructive symptoms and pedunculated type. However, the tumor was too big to pass through the pylorus and to be resected with conventional snare at a time; therefore we decided to do endoscopic piecemeal resection. After applying endoclips to prevent bleeding, the tumor was successfully resected by two pieces with a snare, and there was no evidence of recurrence 5 months after resection.
