Abstract

An unusual prostate-specific antigen (PSA) decrease in a Japanese patient with advanced castration-resistant prostate cancer (CRPC) treated with luteinizing hormone-releasing hormone (LH-RH) antagonist after cerebral bleeding is presented. There have been no previous reports that cerebral bleeding or trepanation/drainage of hematoma decreased PSA level, which would make this the first. The LH-RH antagonist may be only one reason for the PSA decrease. More cases need to be accumulated and further investigation is needed to clarify if intracerebral bleeding or an LH-RH antagonist can decrease PSA in such advanced CRPC cases.

Case Report

We experienced an unusual prostate-specific antigen (PSA) decrease in a Japanese patient with advanced castration-resistant prostate cancer (CRPC). The 63-year-old patient had a long history of prostate cancer with a Gleason score of 9 (5 + 4) and T3aN0M1b, and

had already undergone treatment with combined androgen blockade, ethinylestradiol, prednisolone, estramustine phosphate, zoledronic acid, tranilast, tegafur uracil, docetaxel and strontium. At the maximum level of PSA (1,235 ng/ml), intracerebral bleeding occurred and the patient was hospitalized (fig. 1). Initially, the bleeding seemed to not be severe, so conservative therapy was performed. However, the bleeding began to increase, so trepanation with drainage for cerebral hematoma was performed by neurosurgeons (fig. 1). The PSA level decreased slightly following drainage. Two weeks after drainage, we replaced the luteinizing hormone-releasing hormone (LH-RH) agonist with the LH-RH antagonist degarelix. Surprisingly, the PSA level began to decrease from 873 ng/ml at the time of the first degarelix injection, with a level of 540 ng/ml attained after 4 weeks. During hospitalization, the treatment for prostate cancer was not changed except for the LH-RH antagonist injection. Unfortunately, the patient's condition deteriorated again with intracerebral bleeding, mydriasis and loss of light reflex, and he died 58 days after hospitalization.

Discussion

To our knowledge, there have been no previous reports that cerebral bleeding or trepanation/drainage of hematoma cause a decrease in the level of PSA. However, various acute insults induce a decrease of sex steroids and gonadotropins [1]. Low testosterone and luteinizing hormone are commonly observed in men who suffer burns [2, 3]. Similarly, 39% of hemorrhagic and ischemic stroke patients have been found to have hypogonadism with a low testosterone level [4]. Though it is likely that the intracerebral bleeding affected the PSA level in our case, the decrease may also have been a fluctuation; it is not clear if the testosterone level of this CRPC patient treated with combined androgen blockade could have been reduced more by the intracerebral bleeding. The LH-RH antagonist may have contributed to the 56% decrease in PSA, from 1,235 to 540 ng/ml. Two previous studies indicated that switching from LH-RH agonist to LH-RH antagonist could decrease PSA levels in CRPC patients [5, 6]. Degarelix, which is a recently developed LH-RH antagonist, showed a significantly lower risk of PSA progression or death in a certain population when compared with the LH-RH agonist [7]. The difference in effect between LH-RH agonist and antagonist could be explained by (1) a loss of testosterone surge or a reduction of testosterone, (2) the suppression of follicle-stimulating hormone and (3) a direct effect of the LH-RH antagonist on the LH-RH receptors in the prostate cancer cells [2]. A previous study indicated the possibility of a slight change in testosterone level being a cause of PSA decrease [5]. However, PSA levels in these previous studies were 3–60 ng/ml upon commencement of LH-RH antagonist administration [5, 6]. Our case showed a PSA level of 873 ng/ml when the LH-RH antagonist treatment was started, which is the highest level reported to date. The PSA level decrease in this case may therefore have been caused not only by the testosterone level but other mechanisms as well. Unfortunately, we did not measure either testosterone or follicle-stimulating hormone because we did not expect such a decrease in the level of the PSA. Our case demonstrates the therapeutic potential of LH-RH antagonist to decrease the PSA level in advanced CRPC patients. However, a previous report indicated that switching from LH-RH agonist to antagonist decreased PSA levels in only 3 of 17 prostate cancer patients [5]. Although it is necessary to still investigate the application of switching from LH-RH agonist to LH-RH antagonist because of not much evidence, patients who have already undergone all available treatments, as in this particular case, may be eligible candidates for this approach.
