NextGen Brain Microdialysis: Applying Modern Metabolomics Technology to the Analysis of Extracellular Fluid in the Central Nervous System

Chi-Ya Kao, Elmira Anderzhanova, John M. Asara, Carsten T. Wotjak, Christoph W. Turck

Abstract
Microdialysis is a powerful method for in vivo neurochemical analyses. It allows fluid sampling in a dynamic manner in specific brain regions over an extended period of time. A particular focus has been the neurochemical analysis of extracellular fluids to explore central nervous system functions. Brain microdialysis recovers neurotransmitters, low-molecular-weight neuromodulators and neuropeptides of special interest when studying behavior and drug effects. Other small molecules, such as central metabolites, are typically not assessed despite their potential to yield important information related to brain metabolism and activity in selected brain regions. We have implemented a liquid chromatography online mass spectrometry metabolomics platform for an expanded analysis of mouse brain microdialysates. The method is sensitive and delivers information for a far greater number of analytes than commonly used electrochemical and fluorescent detection or biochemical assays. The metabolomics platform was applied to the analysis of microdialysates in a foot shock-induced mouse model of posttraumatic stress disorder (PTSD). The rich metabolite data information was then used to delineate affected prefrontal molecular pathways that reflect individual susceptibility for developing PTSD-like symptoms. We demonstrate that hypothesis-free metabolomics can be adapted to the analysis of microdialysates for the discovery of small molecules with functional significance.

Introduction
Microdialysis is used to dynamically monitor endogenous and exogenous substances in vivo. The procedure can be performed in any tissue [1] and body fluid [2, 3]. A major focus is the analysis of brain neurotransmission, neurochemistry and metabolism [4, 5], and microdialysis remains the method of choice for experimental neuropharmacology studies by acquiring pharmacokinetic and pharmacodynamic data from living animals [6]. For this purpose, extracellular fluids from selected brain areas are analyzed for molecular components relevant for the...
physiological/pathological processes or drug response. The technique enables an assessment of the release and metabolism of neuroactive endogenous substances over a period of several days in freely moving animals. Sampling of specific brain regions, such as the medial prefrontal cortex (mPFC), paraventricular nucleus and amygdala, during behavioral experiments with rodents can be done with efficient spatial and temporal resolution of millimeters and minutes, respectively, reflecting the actual state of the animal under investigation.

Perfusion of an implanted microdialysis probe with artificial cerebrospinal fluid that resembles the brain extracellular fluid with regard to pH, ion composition and osmolarity is not accompanied by significant fluid gain or loss and tissue homeostasis disturbances, thus making microdialysis a truly physiological method for the purpose of in vivo sampling. By using a semipermeable membrane designed for microdialysis probes, macromolecules such as enzymes and proteins are excluded. This leaves collected extracellular matrices intact. Furthermore, the absence of macromolecular complexes in microdialysates does not require sample purification prior to analysis [5].

Commonly employed methods for the analysis of microdialysates include electrochemical, UV and fluorescence detection coupled with high-performance liquid chromatography (HPLC) as well as radioimmunoassay, enzyme-linked immunosorbent assay, colorimetric and spectrophotometric biochemical assays [1, 7].

The analytical methods currently used have restricted more comprehensive in-depth studies of the precious microdialysate samples. Small sample volumes limit the number of molecules, which can be simultaneously analyzed with good sensitivity using the classical detection methods. For this reason, microdialysate collection times are frequently extended, resulting in poor temporal resolution. Modern analytical methods need to be implemented in order to fully exploit microdialysis sample contents. Liquid chromatography online mass spectrometry (LC-MS) allows selective identification and sensitive quantification of a great number of molecules. Although LC-MS methods have been developed for the identification and quantification in microdialysates of neurotransmitters [8–10], neuropeptides [11] and exogenous compounds such as drugs and their metabolites [12–14], most studies have been restricted to a small number of analytes and consequently have resulted in only narrow insights in pathophysiological mechanisms.

LC-MS has become an important method in the field of metabolomics, the comprehensive analysis of metabolites. When configured in the selected reaction monitoring (SRM) mode, a great number of molecules can be identified with high confidence. This makes LC-MS the method of choice as a comprehensive screening tool for microdialysate analysis and pathway discovery pertinent to pathophysiological responses.

In the present study, we have profiled and monitored central metabolite levels in microdialysates on a large scale for the first time, using an LC-MS metabolomics platform. We have applied this approach to a posttraumatic stress disorder (PTSD) mouse model [15, 16] and have correlated metabolite levels measured prior to foot shock (FS) stress with behavioral readouts of FS resilience (early and delayed post-shock changes in arousal levels). The method is orders of magnitude more comprehensive in terms of qualitative and quantitative molecular information than traditional microdialysate analysis. This information can be exploited to gain a better understanding of pathophysiological mechanisms in mouse models.

### Materials and Methods

#### Animals

Male C57BL/6NCrl mice, 7–8 weeks old, (Charles River GmbH, Sulzfeld, Germany) were housed in groups of four in Makrolon type II cages (23 × 16.5 × 14 cm³) under an inverse 12:12 h light-dark cycle (light off at 7:00) with food and water ad libitum. The experimental procedures were approved by the Government of Upper Bavaria. Laboratory animal care and the experiments were performed in compliance with the European Economic Community recommendations for the care and use of laboratory animals (2010/63/EU).

#### Fear Conditioning and Acoustic Startle Response

Fear conditioning for the PTSD mouse model was performed as described previously [15]. In brief, after 198 s of habituation, the mice perceived two electric FS (1.5 mA, 2 s) with a 60-second interval in between at moderate illumination (40 Lux) in a plexiglass shock chamber. The mice remained in the shock chamber for another 60 s before they were returned to their home cages. To test for arousal levels, acoustic startle response (ASR) was measured automatically as described before [16]. The level of ASR was assessed on days 1 and 2 (ASR1 and ASR2) and FS-stimulated ASR changes (ASR2/ASR1, %) were calculated. For the evaluation of PTSD-like symptoms, the levels of ASR and contextual fear response (CF) were assessed on day 34 (ASR34 and CF34).

#### Brain Microdialysis

Guide cannulas were implanted into the right mPFC (coordinates: AP: +2.20 mm, ML: 0.35 mm and DV: –1.50 mm) in accordance to Paxinos and Franklin’s Mouse Brain Atlas [17] under isoflurane (Abbot, Mumbai, India)/Metacam® (Boehringer Ingelheim GmbH, Ingelheim am Rhein, Germany) anesthesia/anal-
Fig. 1. Outline of the microdialysis experiment in combination with metabolomics applied to a PTSD mouse model. On experimental day 1, ASR1 was measured, followed by fear-conditioning FS1. On experimental day 2, the mice were subjected to recurrent ASR2. Microdialysates collected at Basal 1 were subjected to metabolite profiling. On experimental day 34, PTSD-like symptoms, including ASR and CF, were assessed.

Microdialysis probes with a molecular cutoff of 6 kDa (o.d. 0.2 mm, cuprophane membrane 2 mm of length, MAB 4.15.2. Cu; Microbiotech/se AB, Stockholm, Sweden) were inserted and connected to the perfusion lines, which consist of FEP tubing and low-volume liquid swivel TCS2–23 (Eicom, Kyoto, Japan). From the moment of insertion, the probes were continuously perfused with sterile artificial cerebrospinal fluid (NaCl 145 mM, KCl 2.7 mM, CaCl₂ 1.2 mM, MgCl₂ 1.0 mM and Na₂HPO₄ 2.0 mM; pH 7.4) at a flow rate of 0.3 μl/min.

The microdialysis experiment is outlined in figure 1. On experimental day 1, the mice were kept in the experimental plexiglass home cages (16 × 16 × 32 cm³) lasted for 1 week and included Metacam supplementation (0.25 mg/100 ml) with drinking water for 3 days after surgery, with daily inspection for food intake. One day before the experiment, the mice were shortly anesthetized with isoflurane. Microdialysis or gluconeogenesis and pyruvate metabolism. In addition, the list included a number of central nervous system. The samples were transferred to the perfusion lines, which consist of FEP tubing and low-volume liquid swivel TCS2–23 (Eicom, Kyoto, Japan). From the moment of insertion, the probes were continuously perfused with sterile artificial cerebrospinal fluid (NaCl 145 mM, KCl 2.7 mM, CaCl₂ 1.2 mM, MgCl₂ 1.0 mM and Na₂HPO₄ 2.0 mM; pH 7.4) at a flow rate of 0.3 μl/min for overnight perfusion. The microdialysis experiment is outlined in figure 1. On experimental day 1, the mice were kept in the experimental plexiglass home cages (16 × 16 × 32 cm³) for baseline microdialysis sample collection for 1.5 h. The mice were then subjected to a 20-minute ASR test in a sound and protected environment. To permit a continuous dialysis in microdialysis experiments, we used a custom-made startle chamber equipped with a commercially available ASR apparatus (San Diego Instruments, San Diego, Calif., USA). Response was expressed in arbitrary units. At the end of each test, the mice were transferred back to their home cages, and the chamber was cleaned thoroughly with soap water. Two hours later, the mice were subjected to a FS for fear conditioning. Microdialysis was done as described previously [18]. The microdialysate fractions corresponding to the periods of Basal 1 (samples 1–3), ASR1 (samples 4–7) and FS1 (samples 8–11) on experimental day 1 were collected. Only baseline samples were analyzed for metabolite content.

Statistics and Data Analysis
Metabolites with >20% missing value and z-score >4 were considered outliers and removed from our analyses. We normalized the intensities of each metabolite to have a mean of zero and a standard deviation of 1. Correlation analyses for the metabolite levels and behavioral readouts were performed employing GraphPad Prism 5 (GraphPad Software, La Jolla, Calif., USA). In brief, we correlated Basal 1 metabolite levels with behavioral readouts (ASR2/ASR1, ASR34 and CF34) by calculating the Pearson correlation coefficient. The significant level was set to p < 0.05. Pathway analysis was conducted using MetaboAnalyst pathway tool (http://www.metaboanalyst.ca).

Results
Metabolite Profiling of mPFC Extracellular Fluid
Microdialysate fractions were subjected to high-throughput metabolomics analyses with the help of a targeted LC-MS platform interrogating a list of close to 300 metabolites that encompass several central pathways related to energy metabolism, including citrate cycle, glycolysis or gluconeogenesis and pyruvate metabolism. In addition, the list included a number of central nervous system pathways.
Fig. 2. Linear correlations between Basal 1 metabolite levels and FS-induced behavioral changes. Basal 1 metabolite levels correlated with FS-induced ASR2/ASR1 (a), ASR34 (b) and CF34 (c).

(For Figure 2b and c see next page.)
system-relevant molecules that are typically analyzed in microdialysis experiments including neurotransmitters (glutamate and glycine) and endogenous ion channel agonists/antagonists (aspartate, alanine, kynurenic acid and phenylalanine) (online suppl. table S1; see www.karger.com/doi/10.1159/000381855 for all online supplementary material). In our PTSD mouse model, we were able to quantify 120 metabolites after data filtering and normalization (online suppl. table S1).

**mPFC Metabolic Fingerprints under Basal Conditions Predict FS Impact on Arousal**

Metabolic profiling of prefrontal extracellular fluid allowed us to correlate molecular data with behavioral measures in the PTSD mouse model. We identified several central metabolites, which showed linear correlations with the FS-related early changes in arousal (ASR2/ASR1; fig. 2a). We then subjected the metabolites that predicted the FS-induced arousal changes and the highly correlating expression profile metabolites (online suppl. table S2) to pathway analyses. Citrate cycle metabolism and glyoxylate and dicarboxylate metabolism were significantly enriched (table 1). These findings demonstrate the power of metabolite profiling for predicting early behavioral consequences of FS and investigating affected pathways in the PTSD mouse model.

**mPFC Metabolic Fingerprints under Basal Conditions Predict Long-Term PTSD-Like Symptoms**

In addition to the identified correlations for FS-induced early changes in arousal, a number of central metabolites showed prediction power for longer-term PTSD-symptoms, including ASR and CF 34 days after FS (fig. 2b, c). Basal 1 xanthurenic acid and glucose-1-phosphate levels positively predicted ASR34, while sarcosine levels negatively predicted ASR34. Basal 1 spermidine levels negatively predicted the CF34 outcome.

Discussion

The analysis of brain microdialysate samples from individual mice with an LC-MS metabolomics platform enabled us to detect and quantify the levels of close to 120 metabolites. Our approach significantly extends the spectrum of microdialysate analytes and is able to delineate molecular pathways involved in pathological changes related to brain metabolism in a mouse model for PTSD. Metabolomics data analysis revealed numerous correlations between basal mPFC metabolite profiles and FS-associated arousal and contextual fear. Our results demonstrate that combining microdialysis with LC-MS provides a sensitive approach of a high-prediction power for deciphering the molecular signatures associated with individual susceptibility for developing PTSD-like symptoms in a given brain region. In an extension of this approach, microdialysis experiments could provide important insights into affected brain circuits underlying pathophysiological mechanisms by targeting different brain regions.

Microdialysis has been widely applied for the evaluation of extracellular dynamics of neurotransmitters and pharmacological substances in defined brain regions. Targeted quantification of up to 20 monoamines and their metabolites from microdialysis is feasible but provides rather limited insights for specific biological questions [18]. Microdialysis is also routinely used to explore changes in the extracellular levels of neuroactive amino acids including aspartate, glutamate, glutamine and alanine that are relevant not only for neurotransmission focused studies but also for neurotoxicity experiments [19, 20]. However, for sensitivity reasons, the electrochemical or fluorescent detection of amino acids in microdialysates requires pre- or post-column derivatization, which can lead to sample loss and/or measurement variability. In the present study, we were able to quantitate all 20 natural and several additional modified amino acids without derivatization by applying modern metabolomics LC-MS technology as readout for the comprehensive profiling of brain microdialysates (online suppl. table S1). This allowed us to reveal significant amino acid pathways affected by stressors and associated with PTSD-like symptom severity (table 1).

In an earlier study [21] applying the same experimental design, no significant linear correlations were found between basal prefrontal norepinephrine and corticosterone levels and behavioral responses to stress. When analyzing the here presented metabolomics data, Pearson correlation analysis showed prediction power for the metabolites with regard to behavioral changes of the PTSD mice (fig. 2). The correlations between baseline metabolite levels and FS-induced arousal and PTSD-like symptoms demonstrate the power of microdialysate metabolite profiling for the investigation of interindividual variability, in this case susceptibility or resilience towards coping with psychophysiological stress and the development of PTSD endophenotype, in an inbred mouse strain.

Several of the metabolites that show correlations to the early (day 2) and delayed (day 34) behavioral changes induced by stress have relevance for psychiatric phenotypes. Sarcosine, a glycine reuptake inhibitor, has been implicated in the regulation of synaptic plasticity, memory and cognition [22]. Our data show a positive correlation between Basal 1 sarcosine levels and FS-induced ASR2/ASR1. On the other hand, Basal 1 sarcosine levels negatively predicted the FS-induced ASR34. These data suggest that sarcosine-dependent prefrontal mechanisms of plasticity show biphasic dynamics with respect to arousal state regulation. We were also able to quantify neurokynurenines, including kynurenic acid, xanthurenic acid and nicotinate from prefrontal microdialysates. The kynurenine pathway is the major route for tryptophan metabolism and has been implicated in the pathophysiology of depression and stress-related disorders [23, 24]. Mice subjected to unpredictable chronic mild stress exhibited an elevation of the peripheral kynurenine pathway [25]. In the same study, a correlation between the peripheral kynurenine/tryptophan ratio and anxiodepressive-like behavior in mice subjected to unpredictable chronic mild stress was found. Previous studies showed that treatment with nicotinate resulted in improved human sensory register and short-term memory, possibly by facilitating neurotransmission [26]. By binding with neuronal transporters, nicotinate can be utilized as cellular precursor for nicotinamide adenine nucleotide and nicotinamide adenine dinucleotide phosphate synthesis, key events in regulating energy metabolism that has been implicated in the pathogenesis of psychiatric disorders [27–29]. In the current study, we found prefrontal nicotinate levels to positively correlate with FS-induced ASR2/ASR1 change and xanthurenic acid levels to positively predict the arousal response 34 days after shock (ASR34). These results support a possible role for neurokynurenines in mediating neuronal activity, specifically relevant for arousal mechanisms.

An additional benefit of using a great number of analytes for the interrogation of microdialysates is the ability to get information about affected molecular pathways relevant for symptom development in the mouse model under investigation. When subjecting the enriched metabo-
lites to pathway analyses, we found energy metabolism, specifically the citrate cycle pathway, to be affected in the PTSD mouse model. Previous studies have shown increased citrate cycle activity in synaptosomes of high-anxiety mice [30]. Functional synapses are enriched with mitochondria, which supply ATP and regulate calcium levels, modulating neuronal transmembrane potential [31], synaptic neurotransmission [32], receptor signaling [33] and synaptic plasticity [34]. A dysregulated citrate cycle metabolism leads to abnormal energy production that can impair neurotransmission. This may be of particular relevance in the mPFC, which exerts top-down control of emotional states. Anxiolytic medications such as monoamine oxidase inhibitors were shown to improve mitochondrial function [35]. Based on our findings, we assume that differential regulation of the citrate cycle may be involved in endophenotype-specific neurotransmission in the PTSD mouse model.

With the help of the LC-MS metabolomics platform, we were also able to quantify a number of metabolites that are directly related to neurotransmission, including glutamate, hydroxyphenylacetic acid, phenylalanine, tryptophan and the N-methyl-D-aspartate receptor agonists alanine and aspartate. Further applications of the LC-MS metabolomics platform could include studies of neurotransmitter dynamics and help delineate affected pathways involved in neuronal plasticity.

LC-MS microdialysate analysis yields high sensitivity and selectivity compared to the commonly used detection methods [36]. The method allows a reliable qualitative and quantitative determination of a wide range of metabolites. With the help of the LC-MS metabolomics platform, we were able to reveal alterations in intracellular metabolic pathways reflected as changes in metabolite profiles in the extracellular fluid. The method enables hypothesis-free physiological studies, is applicable to any rodent model and may illuminate novel targets for pharmacological intervention.
