Editorial Introduction

The VIIth International Congress of Radiology in ORL took place in Copenhagen, in June 1976. The objective of this congress was to bring together some of the people who are well-known by their previous scientific papers and who show a special interest in radiology in ORL. For the first time the computed axial tomography scanners have been
discussed with a possibility to make progress in ORL diagnosis with less strain on the patient. A great number of papers are related to this subject. Wellknown ORL specialized X-ray doctors have given their informations about the experiences in this field of X-ray diagnosis. Undoubtedly this is a new area in radiology in ORL and the experiences to be achieved from these first papers concerning CAT scanners will increase and renew the research within this field in diagnostic radiology. The diagnostic possibilities with the polyme and the stratomatic machine in tomography of tumors of the rhinopharynx, lesion of the facial canal and in Menire's disease are discussed. It has been demonstrated that these apparatuses will improve and increase the diagnosis in our daily work.
