Extramammary Paget's disease · RANKL · MMP7 · MMP25 · CCL5

Abstract

Ectopic extramammary Paget's disease (EMPD) is a rare variant of EMPD that develops in nonapocrine regions. Since reports about ectopic EMPD are limited, little is known about the biological and immunological background of ectopic EMPD. In this report, we present a case of ectopic EMPD on the lower abdomen that expressed RANKL but lacked the expression of MMP7. As we previously reported, Paget's cells express RANKL and MMP7, release soluble RANKL in the tumor microenvironment, and stimulate tumor-associated macrophages to produce tumor-loading factors in conventional EMPD. In our present case, both CCL5-expressing cells and MMP25-bearing cells were lacking, whereas substantial numbers of CCL5-expressing cells and MMP25-bearing cells were found in conventional EMPD. Our case suggested that the lack of MMP7 on Paget's cells might be one of the possible explanations for the biology of ectopic EMPD.

Introduction

Ectopic extramammary Paget's disease (EMPD) is a rare variant of EMPD that develops in nonapocrine regions [1]. Since reports about ectopic EMPD are limited and, to our

knowledge, only 15 cases have previously been reported in the English literature [1–4], little is known about the biological and immunological background of ectopic EMPD. In this report, we present a case of ectopic EMPD on the lower abdomen that expressed RANKL but lacked the expression of MMP7.

Case Report

A 66-year-old woman presented to our Department with a 8-month history of asymptomatic erythema on the lower abdomen. On her initial visit, physical examination revealed a brown-red plaque on the right side of the mons pubis (fig. 1A). The size of the tumor was approximately 20 × 20 mm in diameter. Skin biopsy revealed rounded cells that were devoid of intracellular bridges and a large nucleus in the epidermis (fig. 1B). Immunohistochemical staining revealed that these tumor cells were positive for CK7, PAS, GCDPF-15, Alcian blue, as well as RANKL (fig. 2A), and negative for CK20 and MMP7 (fig. 2B). In addition, CD163⁺ tumor-associated macrophages (TAMs) were detected adjacent to the Paget's cells in the dermis (fig. 2C). From the above findings, we diagnosed this case as RANKL-expressing ectopic EMPD. There was no significant enlargement of the bilateral inguinal lymph nodes. We resected the tumor with a 1-cm surgical margin. We screened for a possible internal malignancy with computed tomography scan and found no evidence of metastasis.

To further investigate the immunological background of our case, we employed immunohistochemical staining of CCL17, CCL5, and MMP25, both of which are reported to be increased on macrophages by the stimulation of soluble (s)RANKL [5], for our present case and 5 cases of conventional EMPD. Substantial numbers of CCL17-expressing cells (fig. 3A), CCL5-expressing cells (fig. 3C), and MMP25-bearing cells (fig. 3E) were detected in the conventional EMPD, whereas few CCL17-expressing cells (fig. 3B), CCL5-expressing cells (fig. 3D), and MMP25-bearing cells (fig. 3F) were detected in the present case.

The following antibodies (Abs) were used for immunofluorescence staining: mouse monoclonal anti-human CD163 Ab (clone: 10D6; Novocastra, UK), and anti-human CCL5 Ab (clone: 50013–5; LifeSpan BioScience, Seattle, Wash., USA), rabbit polyclonal anti-human RANKL Ab (LifeSpan BioScience), anti-human MMP7 Ab (LifeSpan BioScience), and anti-human MMP25 Ab (Abcam, Tokyo, Japan), and goat polyclonal anti-human CCL17 Ab (R&D Systems, Tokyo, Japan).

Discussion

Together with regulatory T cells (Tregs), TAMs play critical roles in maintaining the immunosuppressive tumor microenvironment by producing various chemokines, including Th2-related chemokines, such as CCL5 and CCL17, in the lesional skin of EMPD [5–7]. CCL5 is a chemokine that plays a role in polarizing naive T cells to Th2 cells through CCR3 signaling pathways [8]. CCL5/CCR3 signaling promotes metastasis by inducing the Th2 polarization of CD4⁺ T cells and determines the prognosis of luminal breast cancer [9]. On the other hand, CCL17 derived from TAMs stimulated by RANKL plays a crucial role in the recruitment of Tregs to the tumor site to maintain the immunosuppressive tumor microenvironment [8]. Taken together, TAMs in EMPD develop an immunosuppressive microenvironment by producing of tumor-loading chemokines.

Among the series of matrix metalloproteinases (MMP), MMP25 is upregulated by the stimulation of RANKL on monocytes-derived macrophages [5]. MMP25 degrades types I–IV collagens, gelatin, fibronectin, and fibrin, and is reported to correlate with tumor migration, tumor invasion, and prognosis of several types of cancer [10, 11].

Unlike conventional EMPD, immunohistochemical staining in the present case revealed the expression of RANKL but the lack of expression of MMP7 on Paget's cells. As we previously reported, Paget's cells express RANKL and MMP7 [6, 12], release sRANKL in the tumor microenvironment [6], and stimulate TAMs to produce Tregs-related chemokines, such as CCL17, in conventional EMPD [7]. Therefore, the lack of MMP7 might abrogate the release of sRANKL, leading to the downregulation of chemokines and MMPs from TAMs. Indeed, CCL17-expressing cells, CCL5-expressing cells, and MMP25-bearing cells were lacking in the present case. Notably, to our knowledge, there is no report in the English literature that describes metastatic ectopic EMPD [1–4]. The lack of MMP7 on Paget's cells might be one of the possible explanations for the biology of ectopic EMPD. Since this report presents a single case, further analysis of the mechanisms underlying this phenomenon may provide fundamental insights into the biology of ectopic EMPD. Such issues will need to be clarified in future investigations.
