Abstract

Neurological involvement in relapsing polychondritis (RP) is relatively rare. We describe the case of an 80-year-old man who presented with hypertrophic pachymeningitis (HP) together with arthritis as the first manifestation of RP. Auricular chondritis, which subsequently determined the diagnosis of RP, occurred a few weeks after the detection of HP. The neurological symptoms, as well as arthritis, were promptly improved by treatment with corticosteroids. It is generally difficult to diagnose RP in the absence of typical cartilaginous involvement; however, the present case suggests that HP may occur as an early clinical manifestation of RP.

Introduction

Relapsing polychondritis (RP) is an autoimmune disease that affects cartilaginous tissue and proteoglycan-rich structures causing chronic inflammation [1, 2]. Symptoms generally involve the eyes, elastic cartilaginous structures of the nose and ears, respiratory tract including the laryngeal and tracheal cartilage, or hyaline cartilage of joints [3, 4]. The central nervous system is also recognized as an episodic target of RP, resulting in cranial neuropathies, encephalitis, meningitis, and ischemic stroke [5]. However, hypertrophic pachymeningitis (HP), which is an inflammatory disorder that causes focal and diffuse thickening of the dura mater, is uncommon in RP patients. Herein, we describe the case of a patient with RP who presented with HP as an early clinical manifestation of RP. To our knowledge, this is the first case where HP occurred prior to the diagnosis of RP.

Case Report

An 80-year-old man presenting with headache, deafness on the right side, sensory disturbance on the left side of the face, and gait disturbance ascribable to remarkable dizziness, as well as bilateral arthralgia of the wrists, was admitted to our hospital. Magnetic resonance imaging (MRI) of the brain revealed diffuse thickening of the dura mater with gadolinium enhancement on T1-weighted images, in the falx cerebri, convexity, and tentorium cerebelli, which was compatible with HP (fig. 1a, b). In the systemic assessment at admission, no inflammatory findings were demonstrated in the oral cavity, eyes, inner or external ears, skin, upper or lower respiratory tracts, cardiovascular system, digestive system, kidney, or urinary tract, despite bilateral tenderness with mild swelling in the wrist joints and neurosensory deafness. There were no abnormal findings suggestive of malignancy. Blood and biochemical examinations at admission revealed mild increases of white blood cell count (9,200/ μ l) and C-reactive protein (CRP) level (0.85 mg/dl), while results of all serum examinations, including those for rheumatoid factor, anti-nuclear antibodies, anti-dsDNA antibody, anti-SS-A antibody, anti-SS-B antibody, proteinase 3 anti-neutrophil cytoplasmic antibody (ANCA), myeloperoxidase ANCA, and angiotensin-converting enzyme were negative. The IgG4 titer was within the normal range (77 mg/dl). A cerebrospinal fluid (CSF) examination revealed elevation of protein levels (78 mg/dl), pleocytosis (57 cells/ μ l, 100% monocytes), and a high IgG index (1.9) with normal intracranial pressure. No atypical cells were found in cytological examination of the CSF. Tests of infection in the CSF, including cultures for bacterial or fungal infections, and the polymerase chain reaction test for tuberculosis were all negative. Three weeks after the demonstration of HP on MRI, right ear swelling appeared with CRP levels rising to 5.8 mg/dl, and abnormal uptake was observed in the right ear in gallium-67 scintigraphy (fig. 2a, b), resulting in the diagnosis of RP according to the criteria described by Michet et al. [4]. Following the administration of 100 mg intravenous hydrocortisone for 3 days, oral prednisolone was administered at a dose of 20 mg daily, resulting in normalization of the CRP level and an immediate improvement of all symptoms, except for the right-sided deafness, which partially remained. The MRI finding of the gadolinium-enhanced dura mater was also improved (fig. 1c, d). Oral prednisolone was successfully reduced without relapse.

Discussion

Neurological symptoms are recognized as relatively rare complications in RP, especially at the onset of disease [1], when compared with the involvement of auricular, ocular, nasal, respiratory, or cardiovascular systems. Nevertheless, it has been reported that 9.7% of patients with RP developed central nervous system involvement [6]. HP is an inflammatory disorder that occurs secondary to intracranial infections, neoplastic diseases, and some autoimmune disorders such as ANCA-associated vasculitis (AAV), sarcoidosis, and IgG4-related disease [7]. To our knowledge, only four cases of HP related to RP have been reported in two original articles [8, 9] (table 1). However, AAV was also demonstrated in three of those cases, suggesting that AAV might affect the occurrence of HP; incidentally, AAV is the most common cause of HP [7]. Considering the pathogenesis of RP, underlying vasculitis is frequently observed, especially in patients with neurological manifestations [2]. Furthermore, the possible overlap between RP and AAV has been previously indicated [1, 2]. However, our case did not have any other apparent secondary causes of HP during systemic assessment. According to the epidemiological descriptions of RP, concurrent autoimmune diseases, including not only systemic vasculitis but also several connective tissue diseases, are complicated and occur in more than 30% of RP patients [3]. Therefore, the present case may be valuable in order to describe HP related to RP without the interactions of other pathologies.

In another case of HP related to RP, HP occurred more than 1 year after the onset of RP (table 1). Meanwhile, the present case presented with auricular chondritis, which is the representative and most common characteristic of RP [1–4], a few weeks after the appearance of neurological symptoms associated with HP. Ultimately, auricular chondritis together with the persistence of seronegative polyarthritides and neurosensory hearing loss led us to make the definitive diagnosis of RP according to the prevalent criteria [4], although these manifestations were insufficient to fulfill other diagnostic criteria [3, 10]. We recognize that this is the first report of HP related to RP prior to the typical cartilaginous involvement. In the cohort of patients with HP, 44% were classified as idiopathic HP [7], whereas histopathological findings in the dura mater from idiopathic HP patients demonstrated inflammatory cell infiltration, fibrosis, and/or vasculitis, suggesting that the pathogenesis of idiopathic HP might be associated with connective tissue and collagen vascular diseases [11]. Considering these issues, some aspects of idiopathic HP may be the preceding state before the diagnosis of autoimmune diseases. Accordingly, it is suggested that HP may occur as the initial clinical manifestation of RP before the appearance of visible cartilaginous involvement. Although the pathogenesis of RP is still uncertain, T-cell-mediated immunity and inflammatory cytokines, including interleukin-1 β , -6, and -8, are suggested as indicators of RP [12, 13]. In addition, antibodies against the cartilage matrix protein known as matrilin-1 and several types of collagen, such as type II, IX, and XI, have been described as causative agents of RP [14]. Overall, the mechanism of RP could be explained by these candidate immune mediators attacking proteoglycan-rich structure and cartilaginous tissue. Furthermore, the susceptibility of the dura mater tissue may be considered in the pathogenesis of RP. With regards to the anatomical background, the inner surface of the dura mater includes fibroblasts and fine collagen fibers which may consist of proteoglycans [15]. Accordingly, the dura mater also has an affirmative component to the pathogenesis of RP. However, a definitive relationship between these causative agents and the histological background of the dura mater has yet to be demonstrated.

It is usually difficult to make a definitive diagnosis of RP before the appearance of the typical cartilaginous involvement. Moreover, the specific symptoms for determining the

diagnosis of RP are not entirely seen during the early phase of disease [2]. The present case suggests that HP may occur as the initial manifestation of RP. However, it is necessary to accumulate additional clinical experience and explore the immunopathological mechanisms in order to clarify the details of this disease.
