Abstract

Metastases of transitional cell carcinoma (TCC) of the renal pelvis to the eye is a very rare event, as only one previous case has been described in the literature. We present a patient with choroidal metastasis secondary to TCC of the renal pelvis, with a review of the relevant literature. A 61-year-old male presented with sudden-onset loss of vision of the left eye. Upon evaluation and assessment, the patient was found to have unilateral choroidal metastasis secondary to TCC of the renal pelvis. He is currently on palliative chemotherapy with carboplatin and gemcitabine. External beam radiation therapy is a common mode of treatment and will be considered accordingly.

Introduction

Metastasis of transitional cell carcinoma (TCC) of the renal pelvis to the eye is a very rare event and has only been reported in one case in the literature [1]. Once diagnosed, these

cases usually show widespread metastases and carry a very poor prognosis [2]. We present a case report of a male patient with unilateral choroidal metastasis secondary to TCC of the renal pelvis. Review of the relevant literature will be addressed to highlight the involvement of the choroid in cases of metastatic disease, the unusual presentation of TCC, diagnostic methods, and the various therapeutic modalities used to treat these cases.

Case Report

A 61-year-old male, who has a history of congestive heart failure, is a nonsmoker, and has no significant family history of malignancies, presented to the ophthalmology clinic with sudden-onset loss of vision of the left eye associated with intermittent left eye pain, relieved by analgesics. Ophthalmic evaluation revealed a visual acuity of 20/40 in the right eye and 20/400 in the left eye. Slit-lamp examination revealed a normal anterior chamber, except for bilateral cataracts. Funduscopy examination of the left eye showed an amelanotic macular choroidal lesion associated with inferior exudative retinal detachment (Fig. 1a). Funduscopy examination of the right eye was unremarkable. A B-scan ocular ultrasound showed a dome-shaped, 2.8-mm choroid thickening with variable internal reflectivity, associated with inferior exudative retinal detachment (Fig. 1b). Optical coherence tomography revealed subretinal fluid. Fluorescein fundus angiography revealed early choroid blockage (Fig. 1c) and late leakage associated with hot spots at tumor margin. All of these clinical features are suggestive of the clinical diagnosis of left choroidal metastasis.

Physical examination of the patient also revealed multiple suspicious chest wall nodules. In search for a primary malignancy, imaging studies were done, which revealed multiple pulmonary and liver metastasis, subcutaneous metastasis, multiple lymphadenopathies, and left renal upper pole mass (Fig. 2). CT-guided left renal mass biopsy and ultrasound-guided biopsy of the left chest wall subcutaneous mass were performed. The histopathological examination revealed tumor consistent with transitional cell carcinoma in both biopsies. The tumor cells are positive for CK7, CK5/6, GATA3, and PAX8. They are negative for CK20, PAX2, TTF-1, synapophysin, and S100 (Fig. 3).

The patient was started on palliative chemotherapy with carboplatin and gemcitabine. Restaging images will be done following cycle 3 of chemotherapy. External beam radiation therapy (EBRT) is a common mode of treatment [3] and will be considered if there is no improvement of visual symptoms with chemotherapy.

Discussion

Choroidal metastasis is the most common intraocular malignancy, due to its rich vascular supply and high oxygen concentration [4, 5]. It is often secondary to breast cancer and lung cancer. Less common primary cancers include the thyroid, prostate, kidney, testicles, pancreas, ovary, and liver [6]. Rarely is it seen in cases of TCC, as there have only been 5 previous reports in the literature involving choroidal metastasis, 3 from tumors involving the bladder, and 2 from other parts of the urinary tract [7].

Choroidal metastasis is commonly associated with disseminated disease and, unfortunately, carries a very poor prognosis [2]. TCC usually metastasizes to the regional lymph nodes (78%), liver (38%), lung (36%), bone (27%), adrenal gland (21%), and intestine

(13%) [8]. The heart, brain, kidney, spleen, pancreas, meninges, uterus, ovaries, prostate, and testes have been reported as unusual sites of presentation of TCC [8].

Clinically, patients with choroidal metastasis typically present with blurred vision (81%). Other less common clinical presentations include flashes (5%) and floaters (5%) [9]. Diagnosis is based on clinical findings, which are typically seen as yellow, plateau-shaped lesions associated with subretinal detachment [10]. A-scan and B-scan ultrasonography show irregular internal reflectivity and a solid plateau-shaped mass, respectively. Fluorescein fundus angiography typically shows mottled hypofluorescence in early stage and leakage in late stage [11]. Further studies are usually carried out in search for a primary tumor.

The treatment of choroidal metastasis should be individually tailored, taking into consideration the patient's systemic state, disease activity, and the presence of visual symptoms. Its aim is palliation, to improve the quality of life of the patient and to restore or maintain visual function [12]. Local therapeutic regimens include EBRT, plaque radiotherapy, and complete enucleation for painful, blind eyes [13, 14]. EBRT delivered at a dose of 40 Gy over 20 fractions was effective in improving and maintaining vision in patients with choroidal metastasis [15, 16]. In cases of widespread metastases, systemic chemotherapy alone or in combination with local therapy is an accepted therapeutic option. In patients with choroidal metastasis alone, local therapy has been reported to be safe, maintaining visual functions without the systemic side effects of chemotherapy [14].

Conclusion

Choroidal metastasis related to TCC of the renal pelvis is an extremely rare event and is associated with widespread disease and a very poor prognosis. Systemic chemotherapy with carboplatin and gemcitabine is a palliative treatment option for this patient. EBRT offers local palliation and will be considered according to the patient's visual response to chemotherapy.
