Abstract

Purpose: We present an atypical case of submacular fluid leading to serous macular detachment. **Method/Patient:** A 69-year-old man was evaluated for metamorphopsia in the left eye. **Results:** Best-corrected visual acuity was 20/25 in both eyes. He had undergone cataract surgeries in both eyes 12 years ago. The axial length was 25.93 mm (OD) and 24.12 mm (OS). Optical coherence tomography showed posterior staphylomas and subretinal fluid on the superior border of the staphylomas in both eyes; in the left eye, submacular fluid was noted extending up to the macula. Fundus fluorescein angiography revealed leakage from the superior border of the staphylomas in both eyes. The fluid persisted for 4 months. Four consecutive, monthly injections of bevacizumab (1.25 mg/0.05 mL) were administered in the left eye; subsequently, the subretinal fluid gradually dissipated from the macula and became localized at the superior border of the staphyloma. This localization persisted for 12 months. **Conclusions:** We have detailed a case of submacular fluid that spread from the superior

border of the posterior staphyloma in a patient with macular detachment, in whom intravitreal injections of bevacizumab were highly effective in eliminating the fluid.

Introduction

In eyes with tilted disc syndrome (TDS), serous retinal detachment may develop in the macular region because the edge of an inferior staphyloma typically crosses the macular area [1]. Subretinal leakage in myopic eyes with a posterior staphyloma or TDS is a poorly recognized disease entity [2]. Currently, there is no effective treatment for serous macular detachment associated with TDS, although photocoagulation of accessible angiographically leaking areas has been assayed with variable outcomes [3]. On the other hand, intravitreal injection of the antiangiogenic drug bevacizumab has failed to show efficacy in recent reports [4, 5]. Photodynamic therapy has also failed to show efficacy in a recent report [5]. We present our findings on a highly myopic patient with macular detachment that spread from the superior border of the posterior staphyloma who was effectively treated with intravitreal injections of bevacizumab.

Case Report

A 69-year-old man presented with metamorphopsia in his left eye. His medical history included hypertension, chronic sinusitis, and prostatic hypertrophy. His best-corrected visual acuity was 20/25 in both eyes. He had undergone cataract surgeries in both eyes 12 years ago. Both eyes showed mydriasis of only up to 3 mm. The axial lengths were 25.93 mm OD and 24.12 mm OS. Fundus examination showed posterior staphyloma in both eyes, the border of which was located superior and temporal to the macula (Fig. 1a) in both eyes. Optical coherence tomography demonstrated that subretinal fluid (SRF) was located on the superior border of the staphyloma in both eyes; submacular fluid had spread to the macula in only the left eye without choroidal neovascularization or polypoidal lesions (Fig. 2). Fundus fluorescein angiography showed a belt-shaped area of granular hyperfluorescence corresponding to the border of the staphyloma in both eyes (Fig. 1b). The hypofluorescence was more pronounced in the early phase of indocyanine green angiography (Fig. 1c). The patient was prescribed kallidinogenase (150 units/day) for 4 months, but no response was noted. After obtaining informed consent, off-label bevacizumab (Avastin, 1.25 mg/0.05 mL) was injected intravitreally at monthly intervals in the left eye; this procedure was performed 4 times.

At 4 months after the treatment, the SRF dissipated from the macula and became localized at the border of the staphyloma, and metamorphopsia had disappeared (Fig. 3). The SRF localization has persisted for 12 months.

Discussion

The clinical course of this patient suggested that intravitreal injections of bevacizumab for serous macular detachment were highly effective. Anti-VEGF agents have the following 2 effects: antiangiogenesis and inhibition of vascular permeability. Milani et al. [3] reported that intravitreal bevacizumab injections led to the disappearance of an early leaking point on

fluorescein angiography, but optical coherence tomography did not reveal a reduction of serous fluid. In the present case, before intravitreal injections of bevacizumab, the SRF had not changed for 4 months. After 4 consecutive monthly injections of bevacizumab, the SRF decreased and the localization has persisted for 12 months but has not changed. Intravitreal injections of bevacizumab are thought to be effective in reducing choroidal permeability in this case.

In the present case, serous macular detachment occurred due to the spread of SRF from the superior border of the posterior staphyloma. Pardo-López et al. [4] reported that the edges of an inferior staphyloma usually cross the macular area. Typically, SRF with posterior staphyloma is observed when the macula is located on the border of the posterior staphyloma. We consider that it is only under these conditions that patients recognize the symptoms, and there are potentially many unrecognized cases of SRF on the staphyloma border far from the macula. Some reports have named this disease TDS [3, 6]. We agree that in most eyes, the macula is located on the border of the posterior staphylomas, and the borders also cross the disc, leading to tilted disks. However, this is not a standardized name, and we consider that this clinical manifestation should be termed “serous retinal detachment on the border of the posterior staphyloma.” The alterations of the retinal pigment epithelium and choroidal vascular network could be caused by a change in the curvature at the border of the staphyloma in highly myopic eyes even away from the macula [4]. The development of SRF might thus be related to retinal pigment epithelium dysfunction and/or choroidal permeability [6].

In summary, we have detailed a case of serous macular detachment from the superior border of the posterior staphyloma, in whom intravitreal bevacizumab therapy was used for efficacious and safe treatment. Since this finding is only supported by a single case report, it would be desirable to accumulate further data and figures to demonstrate the potential safety and efficacy of bevacizumab for this condition.
